CSD - 2nd year

1. Explain all the stages of Data Engineering life cycle in detail.

Data Engineering life Cycle:- describes the complete flow of data from creation to its final use for analytics, ML and decision making.

Data Generation:- is the stage where data is created

Data is produced from various sources such as user interactions, business transactions, application logs. At this stage, data engineers understand where data comes from, its format, and how often it is generated.

Data Ingestion:- Ingestion is the process of collecting data from source systems and moving it into storage. Data can be ingested in batch mode or real-time mode.

Data engineers ensure data is collected accurately and reliably.

Data Storage:- After ingestion, data is stored in databases, data lakes or data warehouses.

Data engineers design storage systems that are scalable, secure and cost-effective and also keep raw data safely.

Data Transformation

Raw data is cleaned and processed to make it useful. This includes removing errors, handling missing values and combining data from multiple sources.

Data Engineers convert raw data into clean and structured data.

Data Serving

Processed data is made available to users through data warehouses, dashboards or API s

Data engineers optimize data so it can be easily and quickly accessed by users.

Analytics and Machine Learning

In this stage, data is used by analysts and data scientists for reporting analysis and prediction.

Good quality data helps in accurate insights and models.

Orchestration and Automation

This stage manages the order and timing of data pipelines.

Data engineers automate workflows so that data processes run on time without manual effort.

Monitoring, Security and Governance.

Data pipelines are monitored to detect failures and data quality issues.

Data engineers also ensure data security, privacy and access control.

5. Define Data Management (DAMA). How can business metabata, operational metabata, and reference metadata work together to ensure accurate and reliable data piplelines?

Data Management (DAMA)- According to Data Management Association, Data management is planning, execution and control of policies, processes and practices that manages data throughout its life cycle

The goal of DAMA is to ensure that data is accurate, consistent, secure and useful for business needs.

Role of Metadata in Accurate and Reliable Data Pipelines

Metadata means data about data. Different types of metadata work together to maintain data quality and reliability in data pipelines.

* Business Metadata :- Business metadata explains data in business terms.

Ex:- Business definitions of data fields
ownership of data.

Role :-
→ Helps users understand the meaning of data
→ Ensures consistent interpretation of data
→ Improves trust and correct usage of data

* Operational Metadata :- Operational metadata describes how data is processed and moved in pipelines.

Ex:- Pipeline schedules
Job status and execution time.

Role :-
→ Helps monitor and manage pipelines
→ Detects failures and delays.
→ Ensures smooth pipeline execution.

* Reference Metadata :-

Reference metadata provides standard values and codes used across systems.

Ex:- Country codes, currency codes, status values

Role :-

→ Maintains data consistency across systems
→ Prevents invalid or mismatched values.
→ Supports data validation.

Working Together

When business, operational and reference metadata work together

→ Data meaning is clearly defined
→ Data pipelines run correctly
→ Data remains consistent and accurate.

This collabration ensures reliable and trustworthy data pipelines.

⇒ Data management as defined by DAMA, ensures proper control and usage of data. By combining business metadata, operational metadata, and reference metadata, orginizations can build accurate, reliable and well-governed data pipelines suitable for analytics.

6. Explain different security concerns in the data engineering life cycle in detail? Write about GDPR and HIPAA

Security Concerns in the Data Engineering Life Cycle.

Security is a critical part of the data engineering life cycle because data passes through many stages such as collection, storage, processing and access. Each stage has its own security risks that must be managed carefully.

1. Data Collection and Ingestion :

During data collection, data is transferred from source system to data platforms. Security concerns include unauthorized access, data interception and data tampering.

To address this, data engineer use secure APIs, encryption during data transfer and authentication mechanisms.

2. Data Storage.

Stored data may contain sensitive or personal information. Security risks include data breaches, data loss and unauthorized access.

Security measures include encryption at rest, access control policies, backups, and secure storage system.

3. Data Processing & Transformation

While transforming data, sensitive information may be exposed. Security concerns include accidental data leakage and misuse of sensitive fields. Data engineers apply data marking, anoymization and role-based access control.

Data Access and Serving :-

Data is made available to analysts, applications, and dashboards.
Security risks include misuse of data by unauthorized users.
Security is ensured using user authentication, authorization, audit logs and monitoring.

GDPR (General Data Protection Regulation)

GDPR is a data protection law of European Union designed to protect personal data of individual

→ Requires user consent for data collection
→ Gives individuals the right to access, correct and delete their data.
→ Organizations must ensure data privacy, security and transparency.

HIPAA (Health Insurance Portability and Accountability Act)

HIPAA is a U.S law that protects sensitive healthcare information.

→ Protects Protected Health Information (PHI)
→ Ensures secure storage and transmission of health data.
→ Limit access to authorized personnel only.
→ Requires audit trails and security controls.
